

This is a formalization of SCP's abstract balloting protocol described in Section 3.5 of the IETF draft at:

<https://datatracker.ietf.org/doc/html/draft-mazieres-dinrg-scp-05#section-3.5>

The goal is to then refine this specification to one that closely matches the concrete SCP protocol.

We provide an inductive invariant showing that, by following the 2 “restrictions on voting” described in Section 3.5 of the above document, safety is guaranteed.

Note that it is not true that a validator never votes to commit and abort the same ballot. This can happen when a validator votes to commit a ballot, but then accepts to abort it because a blocking set accepted to abort it. Moreover, it is necessary for liveness to allow this.
